

1 Introduction

Wind turbine wakes matter for the layout of arrays, since a turbine in another's wake makes less power.

The model fits the data reasonably well, and we can see that the wake recovers by $x/D = 3$ in all cases considered here, so the wake recovers quickly.

The deficit follows from the momentum balance,

$$\Delta u = \alpha mc^2 \tag{1}$$

for all cases.

A final paragraph about efficient turbine arrays closes the paper.
